ABSTRACT

In order to utilize solar energy effectively, it is necessary to study on Maximum Power Point Tracking (MPPT) in photovoltaic power generation system. In this paper, single stage photovoltaic power generation system is studied and the mathematical model of photovoltaic array is established under any arbitrary environment. Due to the nonlinear output characteristic of photovoltaic array, fuzzy control is introduced to realize MPPT. It is presented perturb and observe (P&O) of duty cycle for fuzzy control in MPPT control strategy. The simulation is carried out based on the proposed algorithm. Compared with the conventional duty cycle of P&O method, it can track the maximum power point quickly and accurately [1,3].

Keywords: Fuzzy logic control – solar energy - MPPT - Power control.

1. INTRODUCTION

Due to energy crisis and environmental issues such as pollution and global warming effect, photovoltaic (PV) systems are becoming a very attractive solution. Unfortunately, the actual energy conversion efficiency of PV module is rather low. So to overcome this problem and to get the maximum possible efficiency, the design of all the elements of the PV system has to be optimised. In order to increase this efficiency, MPPT controllers are used. Such controllers are becoming an essential element in PV systems. A significant number of MPPT control schemes have been elaborated since the seventies, starting with simple techniques such as voltage and current feedback based MPPT to more improved power feedback based MPPT such as the perturbation and observation (P&O) technique or the incremental conductance technique [2-4]. Recently intelligent based control schemes MPPT have been introduced. In this paper, an intelligent control technique using fuzzy logic control is associated to an MPPT controller in order to improve energy conversion efficiency [5].

2. PRINCIPLE OF MAXIMUM POWER POINT TRACKING CONTROL

The photovoltaic module operation depends strongly on the load characteristics, (Fig.1 and2) to which it is connected [6,7]. Indeed, for a load, with an internal resistance $R_i$, the optimal adaptation occurs only at one particular operating point, called Maximum Power Point (MPP) and noted in our case $P_{max}$. Thus, when a direct connection is carried out between the source and the load, (Fig. 1), the output of the PV module is seldom maximum and the operating point is not optimal. To overcome this problem, it is necessary to add an adaptation device, MPPT controller with a DC-DC converter, between the source and the load, (Fig. 3), [4]. Furthermore, the characteristics of a PV system vary with temperature and insolation, (Fig. 4 and 5) [8, 9]. So, the MPPT controller is also required to track the new modified maximum power point in its corresponding curve whenever temperature and/or insolation variation occurs.

Fig. 1: Current –voltage characteristic of a PV module

Fig. 2: Power –voltage characteristic of a PV module
Many MPTT control techniques have been conceived for this purpose these last decades [2,3]. They can be classified as:

- Voltage feedback based methods which compare the PV operating voltage with a reference voltage in order to generate the PWM control signal of the DC-DC converter [10],
- Current feedback based methods which use the PV module short circuit current as a feedback in order to estimate the optimal current corresponding to the maximum power.
- Power based methods which are based on iterative algorithms to track continuously the MPP through the current and voltage measurement of the PV module. In this category, one of the most successful and used method is perturbation and observation (P&O), which is presented in the next section.

3. P&O CONTROLLER

This controller is introduced briefly here [11-13]. The principle of this controller is to provoke perturbation by acting (decrease or increase) on the PWM duty cycle and observing the effect on the output PV power. If the instant power \( P(k) \) is greater than the previous computed power \( P(k-1) \) then the direction of perturbation is maintained otherwise it is reversed. Referring to figure 2 this can be detailed as follows:

- when \( dp/dv > 0 \), the voltage is increased, this is done through \( D(k) = D(k-1) + C \), (C: incrimination step),
- when \( dp/dv < 0 \), the voltage is decreased through \( D(k) = D(k-1) - C \).

To simulate this P&O algorithm, a boost chopper, as a DC-DC converter which is described by the equations (1), (2) and (3), (Fig. 6), is used.

\[
I_1 = I - C_1 \frac{dv}{dt} \tag{1}
\]

\[
I_b = (1-D)I_1 - C_2 \frac{dv_b}{dt} \tag{2}
\]

\[
V = (1-D)v_b + L \frac{di_1}{dt} \tag{3}
\]

The parameter \( D \) indicates the duty cycle of this chopper, which is the closing time of the switch over one period.

4. FUZZY LOGIC MPPT CONTROLLER

Recently fuzzy logic controllers have been introduced in the tracking of the MPP in PV systems [13-15]. They have the advantage to be robust and relatively simple to design as they do not require the knowledge of the exact model. They do require in the other hand the complete knowledge of the operation of the PV system by the designer.
The proposed FL MPPT Controller, shown in Figure 7, has two inputs and one output. The two FLC input variables are the error $E$ and change of error $CE$ at sampled times $k$ defined by:

$$E(k) = \frac{P_{ph}(k) - P_{ph}(k-1)}{V_{ph}(k) - V_{ph}(k-1)}$$  \hspace{1cm} (4)

$$CE(k) = E(k) - E(k-1)$$  \hspace{1cm} (5)

where $P_{ph}(k)$ is the instant power of the photovoltaic generator.

The input $E(k)$ shows if the load operation point at the instant $k$ is located on the left or on the right of the maximum power point on the PV characteristic, while the input $CE(k)$ expresses the moving direction of this point.

The fuzzy inference is carried out by using Mamdani’s method, (Table 1), and the defuzzification uses the centre of gravity to compute the output of this FLC which is the duty cycle:

$$D = \frac{\sum_{j=1}^{n} \mu(D_j) - D_j}{\sum_{j=1}^{n} \mu(D_j)}$$  \hspace{1cm} (6)

The control rules are indicated in Table 1 with $E$ and $CE$ as inputs and $D$ as the output.

**Table 1: Fuzzy rule table**

<table>
<thead>
<tr>
<th>$E$</th>
<th>$CE$</th>
<th>NB</th>
<th>NS</th>
<th>ZE</th>
<th>PS</th>
<th>PB</th>
</tr>
</thead>
<tbody>
<tr>
<td>NB</td>
<td></td>
<td>NB</td>
<td>NS</td>

</tbody>
</table>

These two variables and the control action $D$ for the tracking of the maximum power point are illustrated in figure 8 [9].

**5. SIMULATION OF THE P&O AND FUZZY LOGIC MPPT CONTROLLERS AND RESULTS**

Figure 3 shows the functional diagram of the simulated photovoltaic system. The DC-DC converter is the boost chopper of figure 6. The previous MPPT controllers P&O and FLC were simulated under the following tests:

- Constant temperature with a rapid and slow increase in the insolation from 500 to 1000W/m²;
- Constant temperature with a rapid and slow decrease in the insolation from 1000 to 800W/m²;
- Constant insolation with a rapid and slow increase in the temperature from 20°C to 30°C;
- Constant insolation with a rapid and slow decrease in the temperature from 40°C to 20°C.

Figures 9 to 17 show the respective results of these tests.
Fig. 9: Variation of the panel power, battery power and the duty ratio D, under standard conditions: temperature (25 °C) and solar insolation (1000 W/m²).

Fig. 10: Wave shape in steady state of the panel and battery power and of the duty ratio signals for a sampling rate of 100 Hz (T = 25 °C and S = 1000 W/m²).

Fig. 11: Fuzzy and P&O controller responses: for a fast solar insolation increase (500 W/m² to 1000 W/m² in 5 s at 25 °C).

Fig. 12: Fuzzy and P&O controller responses: for a slow (120s) solar insolation increase (800 W/m² to 1000 W/m² at 25 °C).

Fig. 13: Fuzzy and P&O controller responses: for a slow (120s) solar insolation decrease (1000 W/m² to 800 W/m² at 25 °C).
Fig. 14: Fuzzy and P&O controller responses: for a fast temperature decrease (40 °C to 20 °C) at 1000 W/m² of solar insolation.

Fig. 15: Fuzzy and P&O controller responses: for a slow (120s) temperature increase (20 °C to 30 °C) at 1000 W/m² of solar insolation.

Fig. 16: Fuzzy and P&O controller responses: for a slow (120s) temperature decrease (30°C to 20°C) at 1000 W/m² of solar insolation.

Fig. 17: Fuzzy and P&O controller responses: for a fast (5s) temperature increase (20 °C to 45 °C) at 1000 W/m² of solar insolation.

6. CONCLUSION

Obviously, it can be deduced that the fuzzy controller is faster than the P&O controller in the transitional state (Fig. 11, 13, 14, 17), and presents also a much smoother signal with less fluctuations in steady state (Fig. 10). In this work, the aim was to control the voltage of the solar panel in order to obtain the maximum power possible from a PV generator, whatever the solar insolation and temperature conditions. Since quite a few control scheme had already been used and had shown some defects, it was necessary to find and try some other methods to optimize the output, fuzzy logic controller seemed to be a good idea. The controllers by fuzzy logic can provide an order more effective than the traditional controllers for the nonlinear systems, because there is more flexibility. A fast and steady fuzzy logic MPPT controller was obtained. It makes it possible indeed to find the point of maximum power in a shorter time runs compared to the well known P&O controller.
